1 HUMIDIFICATION: ADDING WATER

ADIABATIC Humidification

LATENT HEAT & ADIABATIC PROCESS

SENSIBLE HEAT vs LATENT HEAT

Sensible heat is the energy required to change the temperature of a substance with no phase change. The temperature change can come from the absorption of sunlight by the soil or the air itself. Or it can come from contact with the warmer air caused by release of latent heat (by direct conduction). Energy moves through the atmosphere using both latent and sensible heat acting on the atmosphere to drive the movement of air molecules which create wind and vertical motions.

Latent heat is the energy absorbed by or released from a substance during a phase change from a gas to a liquid or to a solid or vice versa. If a substance is changing from a **solid to a liquid**, for example, the substance **needs to absorb** energy from the surrounding environment in order to spread out the molecules into a larger, more fluid volume. If the substance is changing from something with lower density, like **a gas**, to a phase with higher density like **a liquid**, **the substance gives off energy** as the molecules come closer together and lose energy from motion and vibration.

LATENT HEAT & ADIABATIC PROCESS

Rising air cools at the dry adiabatic rate until the air reaches the dew point and condensation (cloud formation) begins. As air continues to rise the latent heat released by condensation reduces the rate of cooling.

LATENT TEMPERATURE & ADIABATIC PROCESS

- ① Phase transition solid \rightarrow liquid. Latent heat of fusion is needed to break solid bonds.
- ② Phase transition liquid \rightarrow gas. Latent heat of vaporisation is needed to break liquid bonds.

HUMIDIFICATION: ADDING WATER

ADIABATIC Humidification

produce cooling because the air evaporation

USE OF HUMIDITY TO CHILL

DIRECT EVAPORATIVE COOLING

A. Direct Evaporative Cooling

When water evaporates in the indoor air, the temperature drops but the humidity goes up. In hot and dry climates, the increase in humidity actually improves comfort. Misting the air has become quite a popular, direct evaporative-cooling strategy. Water under high pressure is atomized into tiny droplets, which then readily evaporate to cool the air.

Water under high pressure is atomized into tiny droplets, which then readily evaporate to cool the air.

This indirect evaporative cooling system uses a roof pond. Note no humidity is added to the indoors.

This indirect evaporation cooling system uses floating insulation instead of a second roof.

Indirect evaporative coolers reduce the indoor air temperature without increasing its humidity.

B. Indirect Earth Coupling

Indirect earth cooling is possible by means of tubes buried in the ground. Sloped tubes and a sump are required to catch condensation. An open-loop system is shown, while a closed-loop system would return the air from indoors. Tubes must be absolutely tight to prevent radon gas or water from entering.

Isothermal Chilling LOW TECH INDIRECT EVAPORATIVE COOLING

IV Earth Cooling

Soil temperature varies with time of year and depth below grade.

Cooling the Earth

In dry climates, soil can be cooled significantly below its natural temperature by shading it and by keeping it wet for evaporative cooling.

Before one deciding for earth-cooling techniques one should check the thermal properties of soil must be considered. The temperature of soil near the surface follows the air temperature and may change from region to region.

B. Indirect Earth Coupling

Indirect earth cooling is possible by means of tubes buried in the ground. Sloped tubes and a sump are required to catch condensation. An open-loop system is shown, while a closed-loop system would return the air from indoors. Tubes must be absolutely tight to prevent radon gas or water from entering.
